```
class employee( mammal,human):  
    def __init__(self):  
        super().__init__()  
  
employee_instance = employee()  
employee_instance.eat()
```

```
Mammal class initialized.  
Mammal is Eating...
```

- Switch the order of inheritance

```
class employee(human, mammal):
```

```
Human class initialized.  
Human is Eating...
```

- From the output we can deduce that only one class instance from the parent classes is instantiated when `super().__init__()` is called and it's the first inherited class
- Therefore when the `eat()` method is called, the corresponding implementation of the first inherited class will get executed
